0.5.2

June 28, 2018

In the last few years digital currencies have successfully demonstrated their ability to become an alternative financial instrument in many different markets. Most of the technologies available at the moment are based on the principles of [Blockchain](#) architecture, including dominating currencies like [Bitcoin](#) and [Ethereum](#). Despite its popularity, Blockchain is not the best possible solution for all scenarios. One such example is for fast micro-payments. [Zold](#) is an experimental alternative that enables distributed transactions between anonymous users, making micro-payments financially feasible and fast. It borrows the “[proof of work](#)” principle from Bitcoin, and suggests a different architecture for digital wallet maintenance, explained in details in the [White Paper](#).

The Market

Since its release in 2009, [Bitcoin](#) from “a libertarian fairy tale” and “a simple Silicon Valley exercise in hype” turned into “a catalyst to reshape the financial system in ways that are more powerful for individuals and businesses alike,” according to [Andreessen](#). Even though [Cheah et al.](#) argues that “the fundamental value of Bitcoin is zero,” it seems that “the question is not whether Bitcoin has value; it already does,” according to [Van Alstyne](#). “The question is whether the efficiencies of a cybercurrency like Bitcoin can be merged with the certainties of an honest central bank.”

The core component of Bitcoin is Blockchain technology, which “ensures the elimination of the double-spend problem, with the help of public-key cryptography” and “coins are transferred by the digital signature of a hash,” explains Pilkington. Very soon after [Bitcoin](#) was created, similar products were introduced, which were also based on the principles of Blockchain, such as [Ethereum](#) by [Buterin](#).

Even though Blockchain is a sound solution to the double-spending problem, there could be other solutions, including different “proof-of-X” alternatives. For example, [Everaere et al.](#) gave a summary of them and introduced their own, [Boyen et al.](#) described “a truly distributed ledger system based on a lean graph of cross-verifying transactions,” recently [IOTA](#), a “tangle-based cryptocurrency,” was launched by [Popov](#), [Hedera](#) claims to be “the world’s first mass-adopted public distributed ledger”, and so on.

The Problems

Zold is also a decentralized digital currency that maintains its ledgers through an unpredictable amount of anonymous and untrustable server nodes, trying to guarantee data consistency. The architecture of Zold is not Blockchain-based. The development of Zold was motivated by the desire to overcome two obvious disadvantages present in the majority of all existing cryptocurrencies:

The first problem is that transaction processing is rather slow. [Current rates](#) for [Bitcoin](#) processing speed is 7 transactions per second (tps) while Paypal handles an average of 115 tps and the VISA network has a peak capacity of 47,000 tps. [Karame et al.](#) says that “Bitcoin requires tens of minutes to verify a transaction and is therefore inappropriate for fast payments.” It is inevitable, since “processing speed is at odds with the security aspects of the underlying proof-of-work based consensus mechanism” according to [Kiayias et al.](#) [Ethereum](#), according to [Fekkes et al.](#), can process “two times more transactions per second than Bitcoin is able to do,” but this still is rather slow.

The second problem, as noted by [Popov](#), is that “it is not easy to get rid of fees in the blockchain infrastructure since they serve as an incentive for the creators of blocks.” [Möser et al.](#) says that “Bitcoin users are encouraged to pay fees to miners, up to 10 cents (of USD) per transaction, irrespective of the amount paid” which especially hurts when transaction amounts are smaller than a dollar. Moreover, according to [Kaskaloglu](#), “an increase in transaction fees of Bitcoin is inevitable.”

Thus, the speed is low and the processing fees are high. Zold was created as an attempt to resolve these two problems.

The Features

First, unlike all other crypto currencies, there is no central ledger in Zold. Each wallet has its own personal ledger. All transactions in each ledger are confirmed by [RSA](#) signatures of their owners. This enables high scalability and performance.

Second, similar to many other digital currencies, including [Bitcoin](#), [Ethereum](#), [Monero](#), [Plancoin](#), [Dero](#), and many others, Zold nodes find consensus by using the CPU power invested by each of them to perform certain expensive and meaningless calculations that result in finding hash suffixes, also known as “proof-of-work,” initially introduced by [Back](#) in 1997. This guarantees data consistency and eliminates a possibility of double-spending.

Third, Zold is a pre-mined digital asset, similar to [Ripple](#), [Cardano](#), [Stellar](#), [NEO](#), and many others. Zold algorithmically limits its total supply, which is 2,15 billion ZLD. To compare, the total supply of some other currencies is: 21m in [Bitcoin](#), 100b in [Ripple](#), 84m in [Litecoin](#), and 19m in [Dash](#). [Bohr et al.](#) explains that cryptocurrencies limit their total supply in order “to protect against inflationary forces,” so does Zold in order to protect its market value.

Forth, the speed of transaction processing in Zold literally has no limits, because all payments are made locally, on users’ machines and then pushed to the network for merging and storing.

Fifth, the cost of transaction processing is lower than what most other payment systems can offer. To process a thousand transactions a user has to pay (approximately) \$500 in Bitcoin, \$300 in [Ethereum](#), \$45 in [Litecoin](#), \$12 in [Ripple](#), and \$9 in Bitcoin Cash. In Zold it is as little as \$4, which makes it one of the most cost effective cryptocurrencies.

The Roadmap

Zold is an open source software product. Its first version was created by [Yegor Bugayenko](#), CEO of [Zerocracy](#). A distributed network of nodes, which are running Zold software, is maintained by anonymous volunteers. The development of further versions and the maintenance of existing ones depends on the activity of GitHub contributors, partially sponsored by [Zerocracy, Inc.](#)

ZLD is not a security certificate. It is a digital utility token, similar to Bitcoin and Ethereum. It is distributed by Zerocracy as a digital gift to those who actively contribute to the development of software and to the maintenance of the network of nodes.

Aside from programming, Zold enthusiasts may contribute thier monetary assets, like US dollars, to any public open source software project managed by Zerocracy. In exchange, they get rewarded with ZLD digital coins. It is planned to distribute 4 million ZLD until the end of 2018 and raise \$4,000,000 as donations for Zerocracy projects.

It is assumed that the market price of ZLD will grow due to its technical advantages and the popularity of Zerocracy platform among programmers and software companies. It is planned to list ZLD in major crypto exchanges, to let its owners convert coins to different digital assets and fiat currencies.
